

ERP Components and the Application in Brain-Computer Interface

Dr. Xun He

Bournemouth University, 12th July 2016

The 1st HCI and Digital Health Forum:
Technologies and Business Opportunities between China and UK

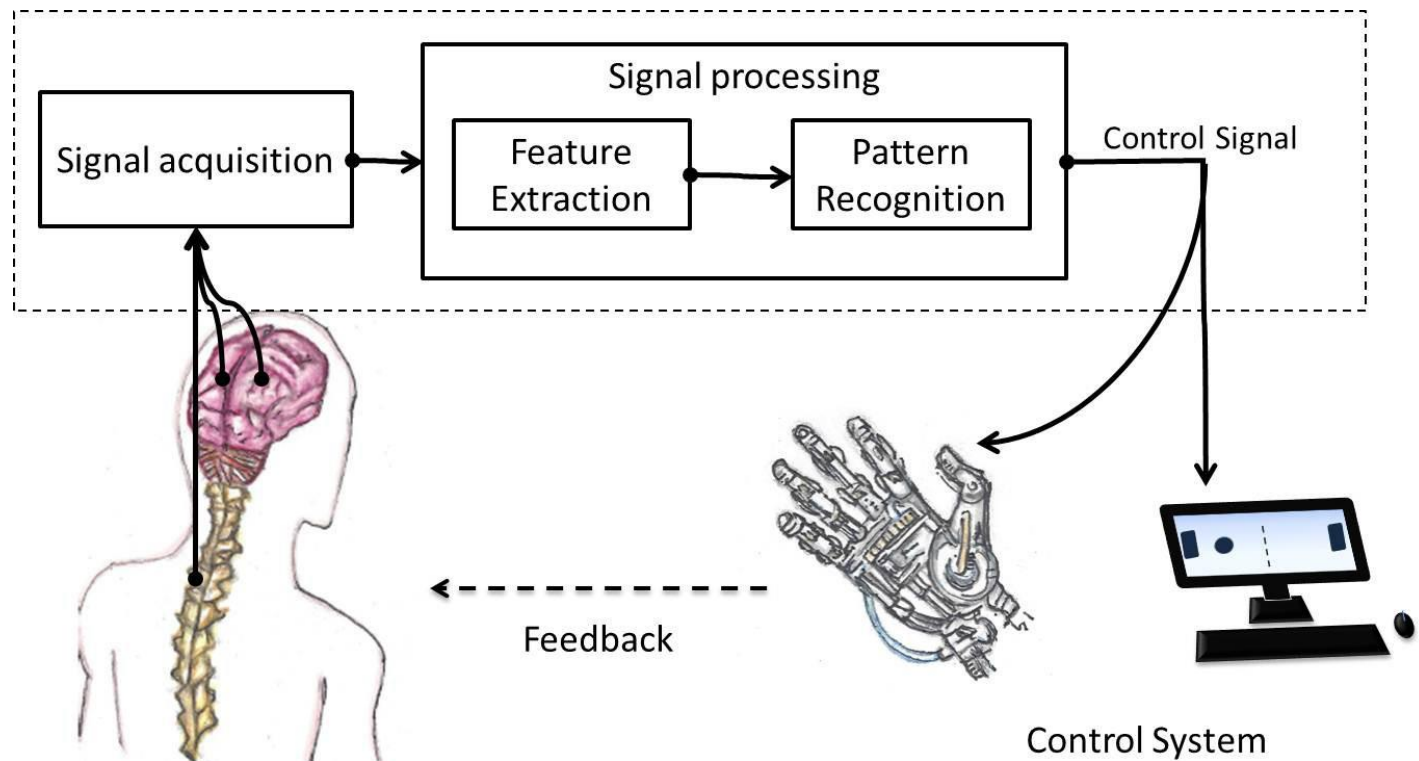

Healthcare needs

- Humans have bodily interaction with the environment mainly with limbs
- Control of limbs impaired due to stroke etc.
- Loss of limbs
- And more...

Brain-computer interface (BCI)

- To control external device using signals from the brain

Electroencephalograph (EEG)

- Brain electrical activities recorded from scalp surface

Electroencephalograph

Why EEG?

- Non-invasive (no implant needed)
- Excellent time information: real-time responses
- Sensitive to mental status

Ongoing EEG in Different States

Application 1

P300 Speller

ERP

Event-related potential (ERP)

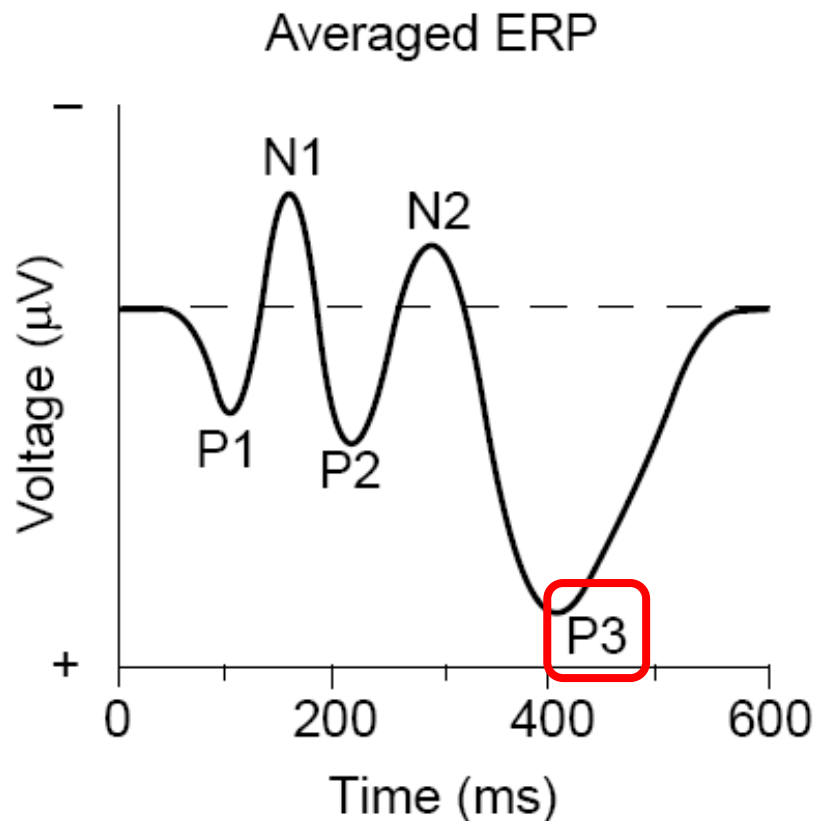

- Electrical responses triggered by sensory, cognitive, or motor *events*, and embedded in EEG
- An event could be a visual/auditory stimulus, an execution of a cognitive function, or a manual response
- ERPs are time-locked to the events (always occurring at the same time relative to the events)

Averaging process

- ERPs are typically generated with an averaging process: responses time-locked to events will remain; noise and responses not time-locked will cancel out

Noise is greatly reduced in ERPs, resulting in much cleaner waveforms (but usually with dozens to hundreds of trials!)

- Averaging is not needed for certain strong ERP activities, such as P3 (also known as P300) in visual ERPs
- This *single-trial* ERP is used in BCI for better efficiency

P300 speller

- Letters are highlighted to generate P300
- ERP recorded from the parietal scalp surface
- Enhanced when the stimulus is attended/desired
- Stronger P300 indicates letter selection

P300 EVOKED POTENTIAL

Usage

- Design 1: letters are organised into groups; once the group is selected, the group will expand for the individual letters to be selected
- Design 2: letters (shown as a grid) will be randomly highlighted one by one
- Design 3: one row or column of the letter grid is highlighted each time (the target is decided by a combination of row and column)

Application 2

Lateralised Readiness Potential (LRP)

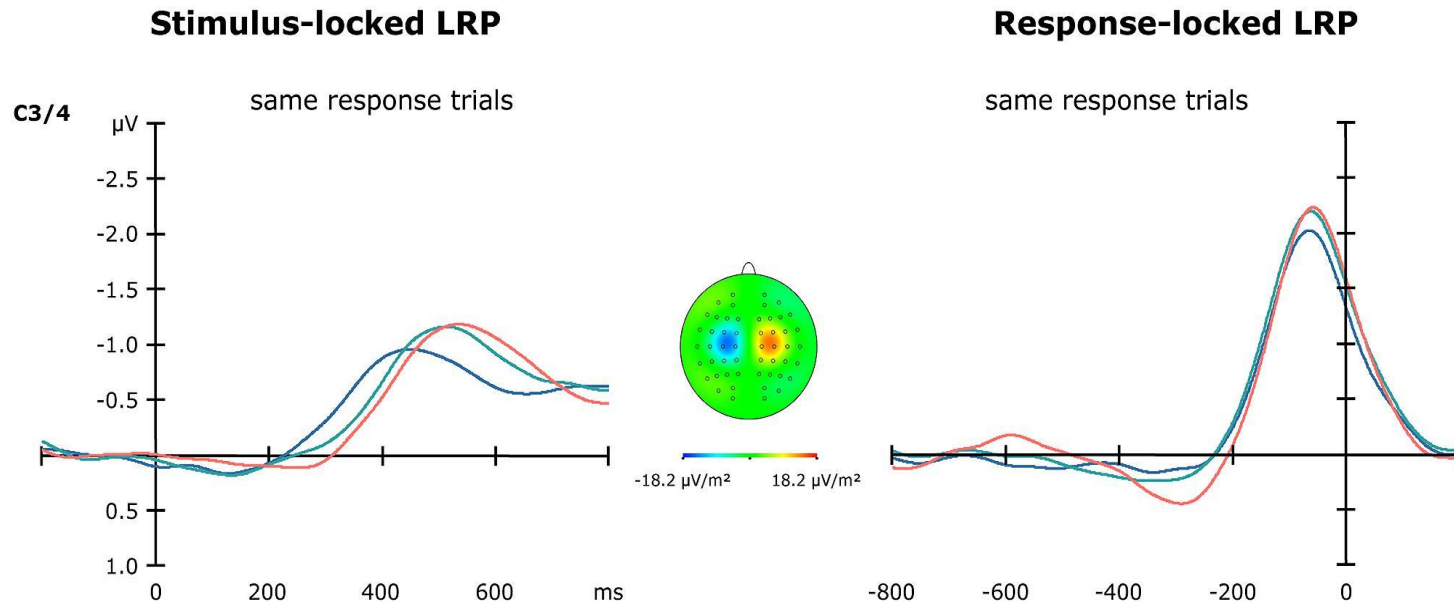

LRP

- Lateralised readiness potential (LRP): ERPs associated with hand movement preparation
- Negativity over the *contralateral* central area of scalp surface (e.g. more negative over the left central area if moving the right hand)

LRP

- Two ways to show LRP: relative to the stimulus onset time or the manual response time
- The LRP occurs before the manual movement is made (therefore the term 'readiness')

No action needed

- LRP is still evident even when people perform *imaginary* movement in their mind
- This means that movement decisions can be detected in LRP's without the need of making the movements

Usage

- Two-option selection: left vs. right
- Less powerful than P300 because LRP is weaker
- Less accurate: currently ~85%
- Advanced algorithms needed to extract the signal

- But, its usage is very natural: no stimulus-selection mapping is needed
- May be the new trend

Application 3

Steady-State Visual Evoked Potential (SSVEP)

SSVEP

- Steady-state visual evoked potential (SSVEP): electrical brain responses to repetitive visual stimuli at specific frequencies (flickers)

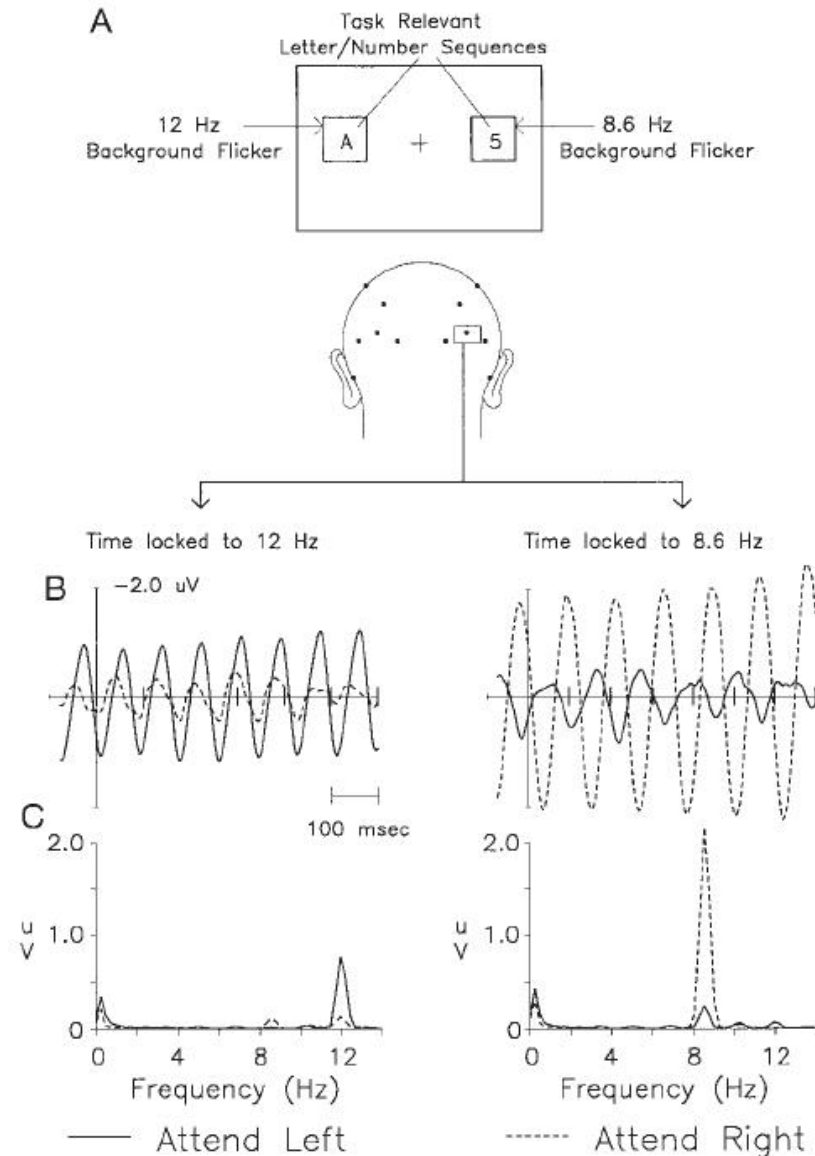

SSVEP

- Can be seen as many superimposed ERP waveforms in response to the repetitive stimuli
- SSVEP has the strongest activity at the stimulation frequency mainly over the posterior scalp surface
- Frequency range: usually 5-80 Hz (higher or lower frequencies generate very weak SSVEPs)

SSVEP

- Nearly sinusoidal oscillatory response having the same frequency as the stimulus
- Sensitive to attention status
- Quantifiable in the frequency domain and can be extracted from background EEG

<https://www.youtube.com/watch?v=PsSPKnD9XsM>

Usage

- Can simultaneously check EEG (SSVEP) responses to several frequencies (multiple choices)
- But it is difficult to discriminate between choices if too many frequencies are used
- Flickering stimuli could be a potential problem for epileptic patients (possibility of inducing epileptic seizures)

To Summarise

ERP is a very powerful tool for BCI with real-time precision

1. P300 speller with letter grid
2. LRP with movement decisions
3. SSVEP with flickering stimulation

Thanks!
